

THE LAZARD FORMAL GROUP, UNIVERSAL CONGRUENCES AND SPECIAL VALUES OF ZETA FUNCTIONS

PIERGIULIO TEMPESTA

ABSTRACT. A connection between the theory of formal groups and arithmetic number theory is established. In particular, it is shown how to construct general Almkvist–Meurman–type congruences for the universal Bernoulli polynomials, that are related with the Lazard universal formal group. Their role in the theory of L -genera for multiplicative sequences is illustrated. As an application, classes of sequences of integer numbers are constructed. Some congruences are also obtained for computing special values of a new class of Riemann–Hurwitz–type zeta functions.

1. INTRODUCTION: FORMAL GROUPS

The theory of formal groups [9], [16] has been intensively investigated in the last decades, due to its relevance in many branches of mathematics, especially algebraic topology [10], [7], [25], [15], the theory of elliptic curves [29], and arithmetic number theory [1], [3], [31], [33].

Given a commutative ring R with identity, and the ring $R\{x_1, x_2, \dots\}$ of formal power series in the variables x_1, x_2, \dots with coefficients in R , a commutative one-dimensional formal group over R is a formal power series $\Phi(x, y) \in R\{x, y\}$ such that [9]

$$1) \quad \Phi(x, 0) = \Phi(0, x) = x$$

$$2) \quad \Phi(\Phi(x, y), z) = \Phi(x, \Phi(y, z)).$$

When $\Phi(x, y) = \Phi(y, x)$, the formal group is said to be commutative (the existence of an inverse formal series $\varphi(x) \in R\{x\}$ such that $\Phi(x, \varphi(x)) = 0$ follows from the previous definition).

As is well known, over a field of characteristic zero, there exists an equivalence of categories between Lie algebras and formal groups. Let V be the valuation ring of a complete ultrametric field \mathcal{K} . Then a commutative diagram of functors holds [28]:

$$\begin{array}{ccc} \text{Analytic Groups} / \mathcal{K} & \longleftrightarrow & \text{Formal Groups} / \mathcal{K} \\ & \nwarrow \nearrow & \\ & \text{Formal Groups} / V & \end{array}$$

Given a formal group law $F(X, Y)$, let $F_2(X, Y)$ denote its quadratic part. The Lie algebra (over the same valuation ring V) associated to F is defined via the identification $[x, y] = F_2(X, Y) - F_2(Y, X)$. This equivalence of categories is no longer true in a field of characteristic $p \neq 0$.

A crucial point is the relation between the *Lazard's universal formal group* and cobordism theory [10], [25], [26]. Indeed, the coefficients c_n of the universal group can be identified with the cobordism classes of $\mathbb{C}P^n$. Let E be a 2-periodic generalized cohomology theory with a complex orientation in degree zero. Then, for each stably almost complex manifold M , we have a fundamental class $[M] \in E^0$. We also have a canonical formal group law F over E^0 , and it turns out that $\log_F(x) = \sum_{k \geq 0} [\mathbb{C}P^k] x^{k+1} / (k+1)$.

In [10] and [23], the relevance of the Lazard group in the discussion of the classical and modern theory of unitary cobordisms has been clarified. A nice connection with combinatorial Hopf algebras and Rota's umbral calculus [27] was found in [7]. A combinatorial approach has been proposed in [5].

In the papers [31], [33] a relation between the universal formal group and the theory of L-series has been established. A new class of Bernoulli-type polynomials, called the *Universal Bernoulli polynomials*, were introduced, and preliminarily studied in [32]. They are Appell polynomials defined via the universal formal group exponential law.

In [21], [22], the universal Bernoulli polynomials have been related to the theory of hyperfunctions of one variable by means of an extension of the classical Lipschitz summation formula to negative powers.

Due to the generality of their definition, the universal polynomials include many (if not all) of the generalizations of the classical Bernoulli polynomials known in the literature. In [1], [3], Kummer-type congruences for the universal Bernoulli numbers have been derived.

Another interesting aspect is represented by the relation between Bernoulli numbers, Hirzebruch's theory of genera, and the computation of Todd classes [18]. Indeed, in the context of complex cobordism theory, let φ be a multiplicative genus in the sense of Hirzebruch, and c_n is the value of φ on the complex projective n -space. Then the generating function $t/G(t)$, where $G(t)$ is the universal formal group exponential (see Definition 1), is the corresponding characteristic power series in Hirzebruch's formalism. For instance, the power series associated to the L -genus, the Todd genus and the A genus are special cases of the proposed construction. Consequently, the generating function defining the polynomials $B_{k,a}^G(x)$ can be interpreted as some special value of the genus.

In this paper, we address the following general problem: *Construct congruences for the Universal Bernoulli polynomials and apply them to compute special values of the related zeta functions.*

Main result. A universal congruence, that generalize the well-known Almkvist–Meurman [4] and Bartz–Rutkowski [8] congruences to the case of the universal Bernoulli polynomials, is proposed. We introduce two families of polynomials related to the characteristic power series of important m -sequences of the genus theory in algebraic topology, that represent nontrivial representations of the universal polynomials. Their arithmetic properties are studied.

A second result, coming from the theory of universal congruences, is a procedure enabling to construct infinitely many sequences of integers and polynomials with integral coefficients.

Finally, we deduce congruences for the values at negative integers of a new class of Hurwitz-type zeta functions, that have been recently constructed in [33]. Work is in progress on a p -adic generalization of the previous theory.

2. THE LAZARD UNIVERSAL FORMAL GROUP, THE UNIVERSAL BERNOULLI POLYNOMIALS AND NUMBERS

We recall some basic definitions, necessary in the subsequent discussion.

Definition 1. *Let us consider the formal group logarithm, over the polynomial ring $\mathbb{Q}[c_1, c_2, \dots]$*

$$(1) \quad F(s) = \sum_{i=0}^{\infty} c_i \frac{s^{i+1}}{i+1},$$

with $c_0 = 1$. Let $G(t)$ be its compositional inverse (the formal group exponential):

$$(2) \quad G(t) = \sum_{i=0}^{\infty} \gamma_i \frac{t^{i+1}}{i+1}$$

so that $F(G(t)) = t$. We have $\gamma_0 = 1, \gamma_1 = -c_1, \gamma_2 = \frac{3}{2}c_1^2 - c_2, \dots$

The Lazard universal formal group law [16] is defined by the formal power series

$$(3) \quad \Phi(s_1, s_2) = G(F(s_1) + F(s_2)).$$

The Lazard ring L is the subring of $\mathbb{Q}[c_1, c_2, \dots]$ generated by the coefficients of the power series $G(F(s_1) + F(s_2))$.

In [31], the following family of polynomials has been introduced.

Definition 2. The universal higher-order Bernoulli polynomials $\widehat{B}_k^{(a)}(x, c_1, \dots, c_n) \equiv \widehat{B}_k^{(a)}(x)$ are defined by

$$(4) \quad \left(\frac{t}{G(t)} \right)^a e^{xt} = \sum_{k \geq 0} \widehat{B}_k^{(a)}(x) \frac{t^k}{k!}, \quad x, a \in \mathbb{R}.$$

Notice that $a = 1, c_i = (-1)^i$, then $F(s) = \log(1+s)$, $G(t) = e^t - 1$, and the universal Bernoulli polynomials and numbers reduce to the standard ones. For sake of simplicity, we will put $\widehat{B}_k^{(1)}(x) \equiv \widehat{B}_k(x)$ and $\widehat{B}_k(0) \equiv \widehat{B}_k$.

The numbers $\widehat{B}_k^{(1)}(0) \in \mathbb{Q}[c_1, c_2, \dots]$ coincide with Clarke's *universal Bernoulli numbers* [13].

The universal Bernoulli numbers satisfy some very interesting congruences. In particular, we recall the universal Von Staudt's congruence [13], that generalize the classical Clausen–von Staudt congruence and several variations of it known in the literature, and the universal Kummer congruence [1]. Both congruences have a distinguished role in algebraic geometry [7], [20].

The universal Bernoulli polynomials (4) possess many remarkable properties. By construction, for any choice of the sequence $\{c_n\}_{n \in \mathbb{N}}$ they represent a class of *Appell polynomials*. It means that, for all $k \in \mathbb{N}$, $D\widehat{B}_k^{(a)}(x) = k\widehat{B}_{k-1}^{(a)}(x)$, where D denotes the standard derivative operator. The binomial property holds:

$$(5) \quad \widehat{B}_n^{(a)}(x+y) = \sum_{m=0}^n \binom{n}{m} \widehat{B}_m^{(a)}(x) y^{n-m}.$$

We also mention that in the paper ([32]), several families of polynomial obtained by specializing eq. (4), i.e. the Bernoulli-type polynomials of first and second kind, as well as related Euler polynomial sequences were studied.

3. GENERALIZED ALMKVIST–MEURMAN CONGRUENCES

3.1. Some universal congruences. The values $\widehat{B}_n^1(0) := \widehat{B}_n$ correspond to the universal Bernoulli numbers [1]. Here we mention only two of their most relevant properties.

i) *The universal Von Staudt's congruence* [13].

Let $\widehat{B}_0 = 1$ and if $n > 0$ is even, then

$$(6) \quad \widehat{B}_n \equiv - \sum_{\substack{p-1|n \\ p \text{ prime}}} \frac{c_{p-1}^{n/(p-1)}}{p} \mod \mathbb{Z}[c_1, c_2, \dots];$$

Let $\widehat{B}_1 = c_1/2$ and if $n < 1$ is odd, then

$$(7) \quad \widehat{B}_n \equiv \frac{c_1^n + c_1^{n-3}c_3}{2} \mod \mathbb{Z}[c_1, c_2, \dots].$$

When $c_n = (-1)^n$, the celebrated Clausen–Von Staudt congruence for Bernoulli numbers is obtained.

ii) *The universal Kummer congruences* [1], [3].

The numerators of the classical Bernoulli numbers play a special rôle, due to the Kummer congruences and to the notion of regular prime numbers, introduced in connection with Fermat's Last Theorem. The relevance of Kummer's congruences in algebraic geometry has been enlightened in [7]. As shown by Adelberg, the numbers \widehat{B}_n satisfy an universal congruence. Suppose that $n \not\equiv 0, 1 \pmod{p-1}$. Then

$$(8) \quad \frac{\widehat{B}_{n+p-1}}{n+p-1} \equiv \frac{\widehat{B}_n}{n} c_{p-1} \mod p\mathbb{Z}_p[c_1, c_2, \dots].$$

We recall that in [11], [12], Carlitz studied Kummer congruences for specific values of the variables c_i .

Interesting congruences modulo prime numbers and for the cases $n \equiv 0, 1 \pmod{p-1}$ have been proved by Adelberg in [2] and by Hong, Zhao and Zhao in [19].

Almkvist and Meurman in [4] discovered a remarkable congruence for the Bernoulli polynomials:

$$(9) \quad k^n B_n \left(\frac{h}{k} \right) \in \mathbb{Z},$$

where $k, h, n \in \mathbb{N}$. Bartz and Rutkowski [8] have proved a theorem which combines the results of Almkvist and Meurman [4] and Clausen–von Staudt. Simpler proofs of the original one proposed in [4] have also been provided in [14] and [30].

The main result of this section is a generalization of the Almkvist–Meurman and Bartz–Rutkowski theorems for the universal polynomials (4).

Theorem 1. *Let $h/k \in \mathbb{Q}$ and $n \geq 0$ integer. Consider the polynomials defined by*

$$\frac{t}{G(t)} e^{xt} = \sum_{n \geq 0} B_n^G(x) \frac{t^n}{n!},$$

where $G(t)$ is a formal group exponential, such that $c_i \in \mathbb{Z}$ for all i . Assume that $c_{p-1} \equiv 0, 1 \pmod{p}$ for all odd primes p , and $c_1 \equiv c_3 \pmod{2}$. Then

$$(10) \quad k^n \widetilde{B_n^G} \left(\frac{h}{k} \right) \in \mathbb{Z},$$

where $\widetilde{B_n^G}(x) = B_n^G(x) - B_n^G$.

Proof. The following lemma is useful in the proof of Theorem 1.

Lemma 1. *Under the assumptions of the Theorem 1,*

$$\sum_{m=0}^{n-1} \binom{n}{m} k^m \widehat{B}_m \in \mathbb{Z}.$$

Proof. Let \mathbb{Z}_p be the ring of rational p -adic integers. We have to show that $\sum_{m=0}^{n-1} \binom{n}{m} k^m \widehat{B}_m \in \mathbb{Z}_p$ for all primes p . Due to the universal congruences (6) and (7), it suffices to assume $p \nmid k$ and $c_{p-1} \equiv 1 \pmod{p}$. A crucial ingredient in the proof is the following congruence, due to Hermite (for n odd) [17] and proved in full generality in [6]:

$$\sum_{\substack{k=1 \\ p-1 \mid k}}^{n-1} \binom{n}{k} \equiv 0 \pmod{p}.$$

Let us distinguish two cases.

a) $p > 2$. Then

$$(11) \quad \sum_{m=0}^{n-1} \binom{n}{m} k^m \widehat{B}_m \equiv - \sum_{\substack{m=1 \\ p-1 \mid m}}^{n-1} \binom{n}{m} k^m / p \pmod{\mathbb{Z}_p}.$$

Since $p \nmid k$ and $p-1 \mid m$, we can use Fermat's Little Theorem, and deduce that $k^m \equiv 1 \pmod{p}$. The result follows by virtue of the congruence 3.1.

b) $p = 2$. Now,

$$(12) \quad \sum_{m=0}^{n-1} \binom{n}{m} k^m \widehat{B}_m \equiv - \sum_{\substack{m=1 \\ m \text{ even}}}^{n-1} \binom{n}{m} / 2 + n/2 \pmod{\mathbb{Z}_2}.$$

Since $\sum_{m=0, m \text{ even}}^n \binom{n}{m} = 2^{n-1}$, we obtain

$$(13) \quad \sum_{m=1, m \text{ even}}^{n-1} \binom{n}{m} = \begin{cases} 2^{n-1} - 2 & \text{if } n \text{ is even} \\ 2^{n-1} - 1 & \text{if } n \text{ is odd} \end{cases}.$$

Now, since $n \equiv 0, 1 \pmod{2}$, we conclude that $\sum_{m=0}^{n-1} \binom{n}{m} k^m \widehat{B}_m \in \mathbb{Z}_2$. □

We return now to the proof of the Theorem 1. We base the proof on the use of the induction principle on n . First observe that the cases $n = 0$ and $n = 1$ are trivial, due to the fact that $\tilde{B}_0(x) = 0$ and $\tilde{B}_1(x) = x$. We assume the property true for indices $m < n$. Then for the index n , we consider the base case $h/k = 0$ and we proceed by induction on $h/k \neq 0$.

By virtue of (5) for $x = \frac{h}{k}$ and $y = \frac{1}{k}$ we get

$$k^n B_n^G \left(\frac{h+1}{k} \right) = \sum_{m=0}^n \binom{n}{m} k^m B_m^G \left(\frac{h}{k} \right).$$

For $h = 0$, the Theorem is obviously true. Assume that it holds for $h \neq 0$. We obtain:

$$(14) \quad k^n \tilde{B}_n^G \left(\frac{h+1}{k} \right) - k^n \tilde{B}_n^G \left(\frac{h}{k} \right) = \sum_{m=0}^{n-1} \binom{n}{m} k^m \tilde{B}_m^G \left(\frac{h}{k} \right) + \sum_{m=0}^{n-1} \binom{n}{m} k^m \hat{B}_m.$$

The induction hypothesis, together with the base case $h/k = 0$ shows that the Theorem holds for all rational numbers h/k . \square

3.2. Related results. The next theorem is a direct generalization of the Bartz–Rutkowski theorem, proved in [8].

Theorem 2. *Under the hypotheses of Theorem 1, we have that if n is even or $n=1$,*

$$(15) \quad k^n B_n^G \left(\frac{h}{k} \right) + \sum_{\substack{p-1|n \\ p \nmid k}} \frac{c_{p-1}^{n/p-1}}{p} \in \mathbb{Z};$$

if $n \geq 3$ is odd

$$(16) \quad k^n B_n^G \left(\frac{h}{k} \right) \in \mathbb{Z}.$$

Proof. If s is a positive integer, then, under the same hypotheses of Theorem 1, we have

$$(17) \quad (k^n - 1) \sum_{\substack{p-1|n \\ p \nmid k}} c_{p-1}^{n/(p-1)} / p \in \mathbb{Z}.$$

This result is a consequence of Fermat's little Theorem: if $s \in \mathbb{Z}$, and $p \nmid s$, then $s^{p-1} \equiv 1 \pmod{p}$. Therefore, if $c_{p-1} \equiv 1 \pmod{p}$ for all primes $p \geq 2$, we deduce the congruence (17).

In order to obtain the result, it is sufficient to combine Theorem 1, the universal von Staudt congruence (6), (7) and (17). \square

Strictly related to the AM theorem is an interesting problem proposed to the author by A. Granville [24].

Problem: To classify the sequences of polynomials $\{P_n(x)\}_{n \in \mathbb{N}}$ satisfying the Almkvist–Meurman property

$$(18) \quad k^n P_n \left(\frac{h}{k} \right) \in \mathbb{Z}, \forall h, k, n \in \mathbb{N}.$$

We shall call this class of sequences the *Granville class*.

We observe that Theorem 1 provides a tool for generating a large class of polynomial sequences satisfying the property (18).

4. THE TODD GENUS, THE L AND A GENUSES AND RELATED UNIVERSAL POLYNOMIALS

In this section, we will show that there exists a close connection between the m -sequences of Hirzebruch’s theory of genera and the Lazard formal group, via the universal congruences previously discussed. To this aim, we will introduce two classes of polynomials related to specific cases of the K -genus of an almost complex manifold, that can be interpreted as particular instances of the construction of universal Bernoulli polynomials.

To fix the notation, let R be a commutative ring with identity, and $\mathcal{R} = R[p_1, p_2, \dots]$ be the ring of polynomials in the indeterminates p_i with coefficients in R . We assume that the product $p_{k_1} \dots p_{k_r}$ has weight $k_1 + \dots + k_r$, so that $\mathcal{R} = \sum_{n=0}^{\infty} \mathcal{R}_n$, where \mathcal{R}_n contains only polynomials of degree n . Consider a *multiplicative sequence* (or m -sequence) of polynomials $\{K_n\}$ in the indeterminates p_i with $K_0 = 1$ and $K_n \in \mathcal{R}_n, j \in \mathbb{N}$. As is well known, a m -sequence is completely determined by the specification of the associated characteristic power sequence $Q(z)$ (see [18] for details).

The polynomials $\{T_k(c_1, \dots, c_k)\}$ of the m -sequence associated with the power series $Q(x) = x/(1 - e^{-x})$ are called the Todd polynomials (here we adopt the conventional notation $x = z^2$ and

$$\sum_{i=0}^{\infty} p_i(-z)^i = \sum_{j=0}^{\infty} c_j(-x)^j \cdot \sum_{i=0}^{\infty} c_i x^i$$

for the relation among the p_i ’s and the c_i ’s).

Now, let M_n is a compact, differentiable of class C^∞ almost complex manifold, and let $c_i \in H^{2i}(M_n, \mathbb{Z})$ denote the Chern classes of the tangent $GL(n, \mathbb{C})$ -bundle of M_n . The K -genus of M_n , denoted by $K_n[M_n]$, is a ring homomorphism with respect to the cartesian product of two almost complex manifolds.

The genus associated with the sequence of Todd polynomials can be introduced in general for an admissible space A , i.e. a locally compact, finite dimensional space, with $A = \cup_{j \in \mathbb{N}} S_j$, where S_j are compact sets. Let us denote by \mathfrak{b} a continuous $GL(q, \mathbb{C})$ -bundle over A , with Chern classes $c_i \in H^{2i}(A, \mathbb{Z})$. The *total Todd class* is given by $Td(\mathfrak{b}) = \sum_{k=0}^{\infty} T_k(c_1, \dots, c_k)$. When $q = 1$ and $c_1(\mathfrak{b}) = t \in H^2(A, \mathbb{Z})$, we have $Td(\mathfrak{b}) = t/(1 - e^{-t})$. For

an almost complex manifold M_n , the Todd genus is defined to be the rational number $T_n[M_n] = Td(\mathfrak{b})^{(2n)}$, where $u^{(2n)}$ denotes the $2n$ -dimensional component of $u \in H^*(M_n)$.

A similar construction applies in relation with the theory of L -genus, which is the genus associated with the m -sequence with characteristic power series $Q(\sqrt{z}) = x/\tanh \sqrt{z}$, and denoted by $L_k(p_1, \dots, p_k)$. The A -genus is associated with the m -sequence with characteristic power series $Q(z) = 2\sqrt{z}/\sinh 2\sqrt{z}$.

The aim of this section is to study the algebro-geometric properties of the m -sequences discussed above. We introduce now two families of polynomials related to the genus of these sequences.

Definition 3. *We shall call λ -polynomials the family of polynomials generated by the characteristic power series associated with the L -genus:*

$$(19) \quad \frac{2te^{yt}}{\sinh 2t} = \sum_{k \geq 0} \lambda_k(y) \frac{t^k}{k!}.$$

The λ -polynomials are particular cases of the Universal Bernoulli polynomials (4); also the Todd polynomials are directly related to the Nörlund Bernoulli polynomials. The next result relates these polynomials with the universal AM congruences.

Proposition 1. *Let $\tilde{\lambda}_n(x)$ denote the polynomials generated by*

$$(20) \quad \frac{2t(e^{yt} - 1)}{\sinh 2t} = \sum_{k \geq 0} \tilde{\lambda}_k(y) \frac{t^k}{k!}.$$

The sequence $\{\tilde{\lambda}_n(x)\}_{n \in \mathbb{N}}$ is in the Granville class.

Proof. It is sufficient to observe that the following identity holds:

$$(21) \quad t/\sinh(t) = t/(e^t - 1) - t/(e^{2t} - 1).$$

Consequently, the sequence $\{\tilde{\lambda}_n(x)\}_{n \in \mathbb{N}}$ satisfies the hypotheses of Theorem 1. The details are left to the reader. \square

The Cauchy formula relates $Q(z)$ with s_n , which is defined to be the coefficient of p_n in the polynomial K_n :

$$(22) \quad 1 - z \frac{d}{dz} \log Q(z) = \sum_{j=0}^{\infty} (-1)^j s_j z^j.$$

A similar construction can be proposed in relation with the A -genus.

Definition 4. *We shall define the α -polynomials to be the family of polynomials generated by the characteristic power series associated with the A -genus:*

$$(23) \quad \frac{2te^{yt}}{\cosh 2t} = \sum_{k \geq 0} \alpha_k(y) \frac{t^k}{k!}.$$

A completely analogous result also holds for the associated polynomials $\{\tilde{\alpha}_n(x)\}_{n \in \mathbb{N}}$.

Proposition 2. *Let $\tilde{\alpha}_n(x)$ denote the polynomials generated by*

$$(24) \quad \frac{2t(e^{yt} - 1)}{\cosh 2t} = \sum_{k \geq 0} \alpha_k(y) \frac{t^k}{k!}.$$

The sequence $\{\tilde{\alpha}_n(x)\}_{n \in \mathbb{N}}$ is in the Granville class.

5. UNIVERSAL CONGRUENCES AND INTEGER SEQUENCES

5.1. Sequences of integer numbers. In this Section, both sequences of integer numbers and Appell sequences of polynomials with integer coefficients are constructed as a byproduct of the previous theory.

Lemma 2. *Consider a sequence of the form*

$$(25) \quad \frac{t}{G_1(t)} - \frac{t}{G_2(t)} = \sum_{k=0}^{\infty} \frac{N_k}{2k!} t^k,$$

where $G_1(t)$ and $G_2(t)$ are formal group exponentials, defined as in formula (2). Assume that $c_{p-1}^{G_1} \equiv c_{p-1}^{G_2} \pmod{p}$ for all $p > 2$ (here $c_n^{G_j}$ denotes the n^{th} coefficient of the expansion associated to G_j , $j = 1, 2$). Then $\{N_k\}_{k \in \mathbb{N}}$ is a sequence of integers.

Proof. The Bernoulli-type numbers \widehat{B}_k^1 and \widehat{B}_k^2 associated with the formal group exponentials $G_1(t)$ and $G_2(t)$, under the previous assumptions must satisfy the classical Clausen–von Staudt congruence for k even, as a consequence of Clarke’s universal congruence (6). For k odd these numbers are also integers or half-integers, due to (7). It follows that the difference $\widehat{B}_k^1 - \widehat{B}_k^2$ for any k even is an integer and for k odd is a half-integer or an integer. The result follows from the definition of $\{N_k\}_{k \in \mathbb{N}}$ in (25). \square

5.2. Applications. a) The characteristic power series obtained as the difference between the power series associated with the L-genus and that one associated with the Todd genus, i.e. $Q(t) = t/\tanh t - t/(1 - e^{-t})$ is the generating function of the sequence

$$(26) \quad 1, 1, 0, -1, 0, 3, 0, -17, 0, 155, \dots$$

b) In [33], realizations of the universal Bernoulli polynomials were constructed by using the finite operator theory [27]. Here we quote two generating functions of these classes of polynomials, related to certain difference

delta operators:

$$(27) \quad \begin{aligned} \sum_{k=0}^{\infty} \frac{B_k^V(x)}{k!} t^k &= \frac{te^{xt}}{e^{3t} - 2e^{2t} + 2e^t - 2e^{-t} + e^{-2t}}, \\ \sum_{k=0}^{\infty} \frac{B_k^{VII}(x)}{k!} t^k &= \frac{-te^{xt}}{e^{4t} - e^{3t} + e^{2t} - 2e^t + e^{-t} - e^{-2t} + e^{-3t}}. \end{aligned}$$

The sequences associated with the generating functions (27) satisfy the classical Clausen–von Staudt congruence. Since $N_k = 2(B_k^{G_1} - B_k^{G_2})$, they can be used to construct integer sequences of numbers and polynomials. Here are reported some representative of generating functions of integer sequences which can be obtained from the previous considerations.

b.1)

$$\frac{t(1 + e^t)}{2(1 + e^t - e^{2t})}.$$

The sequence generated is 2, 6, 39, 324, 3365, 41958, ...

b.2)

$$\frac{t(1 + 2 \cosh t + 4 \cosh 2t - 6 \sinh t)}{(-6 + 8 \cosh t)(2 + \cosh t - \cosh 2t - \sinh t + \sinh 2t + 2 \sinh 3t)}.$$

The sequence generated is -7, 61, -642, 10127, -207110, 5001663, ...

5.3. Polynomial sequences with integer coefficients. As an immediate consequence of the previous results, we can also construct new sequences of Appell polynomials possessing *integer coefficients*.

Lemma 3. *Assume the hypotheses of lemma 2. Then any sequence of polynomials of the form*

$$(28) \quad \left[\frac{t}{G_1(t)} - \frac{t}{G_2(t)} \right] e^{xt} = \sum_{k=0}^{\infty} \frac{N_k(x)}{2k!} t^k$$

is an Appell sequence with integer coefficients.

Proof. The generating function (28), being of the form $f(t)e^{xt}$, has the general structure of an Appell sequence of polynomials. In particular, the coefficients of each polynomial of the sequence inherit the properties of the function $f(t)$. The result follows by applying the previous Lemma 3 to the case $f(t) = \left[\frac{t}{G_1(t)} - \frac{t}{G_2(t)} \right]$. \square

As an example, consider the sequence of polynomials $\{p_n(x)\}_{n \in \mathbb{N}}$, generated by

$$(29) \quad -\frac{te^{-\frac{3t}{2}} \sec h(\frac{t}{2}) [4 + e^t(1 + 2e^t(-1 + e^t))]}{2(-3 + 4 \cosh t)(1 + (-2 + 4 \cosh t) \sinh t)} e^{xt}.$$

It easy to verify that (29) is the generating function of a sequence of Appell polynomials. The first polynomials of the sequence are

$$\begin{aligned} p_0(x) &= -5, & p_1(x) &= 29 - 10x, \\ p_2(x) &= -150 + 87x - 15x^2, \\ p_3(x) &= 1279 - 600x + 174x^2 - 20x^3 \\ p_4(x) &= -17770 + 6395x - 1500x^2 + 290x^3 - 25x^4, \dots \end{aligned}$$

6. A CLASS OF RIEMANN–HURWITZ ZETA FUNCTIONS AND THEIR VALUES AT NEGATIVE INTEGERS

The previous results enable us to compute special values of a new class of zeta functions, recently introduced in [33]. An important particular example of this class is the celebrated Riemann–Hurwitz zeta function. In order to make this Section self-consistent, some necessary definitions are recalled.

6.1. Hurwitz zeta functions and formal groups.

Definition 5. Let $G(t)$ be a formal group exponential, such that $1/G(t)$ is a C^∞ function over \mathbb{R}_+ , rapidly decreasing at infinity. The generalized Hurwitz zeta function associated with G is the function $\zeta^G(G, s, a)$, defined for $\operatorname{Re}(s) > 1$ and $a > 0$ by

$$(30) \quad \zeta^G(s, a) = \frac{1}{\Gamma(s)} \int_0^\infty \frac{e^{-ax}}{G(x)} x^{s-1} dx.$$

When $c_n = (-1)^n$, we obtain the classical Hurwitz zeta function, which converges absolutely for $\operatorname{Re}(s) > 1$ and it extends to a meromorphic function in \mathbb{C} , represented as a Mellin transform

$$\zeta(s, a) = \sum_{n=0}^\infty (n+a)^{-s} = \frac{1}{\Gamma(s)} \int_0^\infty \frac{e^{-ax}}{1 - e^{-x}} x^{s-1} dx.$$

As a consequence of the previous theory, we get the following result, generalizing a classical property of the standard Bernoulli polynomials.

Corollary 1. For any $m \in \mathbb{N}$, the following property holds

$$(31) \quad \zeta^G(-m, a) = -\frac{B_{m+1}^G(a)}{m+1},$$

where $B_m^G(x)$ is the m -th Bernoulli-type polynomial associated with the considered formal group.

The main result of this section is the following interesting congruence for the generalized Riemann–Hurwitz zeta functions (30).

Theorem 3. *Let $G(t)$ be a formal group exponential, such that $c_i \in \mathbb{Z}$ for all $i = 1, 2, \dots$. Assume that $c_{p-1} \equiv 1 \pmod{p}$ for all primes $p \geq 2$, and $c_3 \equiv c_1 \pmod{2}$. Then*

$$(32) \quad nk^n \zeta^G(1-n, h/k) \in \mathbb{Z},$$

for all $h/k \in \mathbb{Q}$ and n odd, $n \geq 3$, and

$$(33) \quad nk^n \zeta^G(1-n, h/k) + n \sum_{p-1|n} \frac{c_{p-1}^{n/p-1}}{p} \in \mathbb{Z},$$

for n even or $n=1$.

Proof. We can use the previous Corollary 1 with $m = 1 - n$ in the property (31). The result is a consequence of the statement of Theorem 2. \square

6.2. χ -universal numbers from Dirichlet characters and congruences. Let us consider now the case of zeta functions depending on a Dirichlet character, associated with formal groups. In the following, given $N \in \mathbb{N}$, we will denote by $\chi(n)$ a *Dirichlet character with conductor N* .

We propose the following definition.

Definition 6. *Let χ be a nontrivial Dirichlet character of conductor N . The Bernoulli χ -numbers $B_{n,\chi}^G$ associated with the formal group G are defined by*

$$(34) \quad B_{n,\chi}^G := N^{n-1} \sum_{a=1}^N \chi(a) B_n^G \left(\frac{a}{N} \right).$$

Similarly, the universal Bernoulli χ -numbers, associated with the Lazard formal group, are defined by

$$(35) \quad \widehat{B}_{n,\chi} := N^{n-1} \sum_{a=1}^N \chi(a) \widehat{B}_n \left(\frac{a}{N} \right).$$

It is possible to define zeta functions related to Dirichlet characters and formal groups via the formula

$$(36) \quad L(G, \chi, s) = \frac{1}{N^s} \sum_{n=1}^N \chi(n) \zeta^G \left(s, \frac{n}{N} \right).$$

The following result provides a congruence for the class of zeta functions (36).

Corollary 2. *Under the hypotheses of Theorem 3, we have for n odd, $n \geq 3$*

$$(37) \quad nN^n L(G, \chi, 1-n) \in \mathbb{Z}(\chi),$$

where $\mathbb{Z}(\chi)$ denotes the integral extension of \mathbb{Z} generated by the values of the non-trivial character χ .

Proof. It is sufficient to invoke the same argument used in Theorem 3. \square

APPENDIX

Here we report the explicit expressions of the first universal Bernoulli polynomials.

$$\begin{aligned}
\widehat{B}_0(x) &= 1 & \widehat{B}_1(x) &= x + c_1/2, & \widehat{B}_2(x) &= x^2 + xc_1 - c_2/2 + 2c_2/3, \\
\widehat{B}_3(x) &= x^3 + 3/2x^2c_1 + (2c_2 - 3/2c_1^2)x + (3c_1^3)/2 - 3c_1c_2 + 3c_3/2, \\
\widehat{B}_4(x) &= x^4 + 2x^3c_1 + (4c_2 - 3c_1^2)x^2 + (6c_1^3 - 12c_1c_2 + 6c_3)x \\
&\quad + 20c_1^2c_2 - 16/3c_2^2 - 12c_1c_3 + 24/5c_4 - 15c_1^4/2, \\
\widehat{B}_5(x) &= x^5 + 5/2x^4c_1 + (20/3c_2 - 5c_1^2)x^3 + (15c_1^3 - 30c_1c_2 + 15c_3)x^2 \\
&\quad + (100c_1^2c_2 - 75/2c_1^4 - 80/3c_2^2 - 60c_1c_3 + 24c_4)x + 105/2c_1^5 - 175c_1^3c_2 \\
&\quad + 100c_1c_2^2 + 225/2c_1^2c_3 - 50c_2c_3 - 60c_1c_4 + 20c_5.
\end{aligned}$$

Acknowledgments

I am indebted to the unknown referee for many useful observations, which improved the quality of the paper.

I wish to thank heartily Prof. D. Zagier for interest in the work and for correcting a wrong statement in an early version of the paper. I am grateful to Prof. A. Granville for suggesting the cited Problem and to Prof. R. A. Leo for many interesting and helpful discussions.

Part of this research work has been carried out in the Centro di ricerche matematiche Ennio De Giorgi, Scuola Normale Superiore, Pisa, that I thank for kind hospitality.

The support from the research project FIS2011–22566, Ministerio de Ciencia e Innovación, Spain is gratefully acknowledged.
